Kharg Island Situational Report — Geospatial Intelligence Dossier: Infrastructure Inventory, Military Strike Assessment, and Strategic Asset Analysis

📅 March 25, 2026 📊 11 datasets

🗺️ Land Use, Building Footprints, Road Network, Search Osm A708, Search Osm 3D31, Global Power, Points of Interest, Search Umbra Sar D3A7, Military Airports, Search Wikipedia Geo 5C50, Geoconfirmed Events

Full-island overview of Kharg Island with all primary data layers rendered: yellow polygons outline OSM land use zones (industrial, recreational, protected area) across the island's 29.21°N–29.27°N extent; cyan/blue circles represent GeoConfirmed OSINT event points and building footprint centroids distributed from the northern bunker zone to the southern tank farm; yellow circles mark Wikipedia geolocated article anchors including Kharg Airport (KHK, labeled upper right) and the Unknown Martyrs Mausoleum (east coast). The Persian Gulf surrounds the island on all sides with characteristically turquoise shallow-water margins, the eastern coast hosting visible export jetty structures; Kharg Christian Monastery is labeled on the western mid-coast and Palmyran Grave in the central interior. The dense concentration of large circular oil storage tanks is

visible across the southern third of the island, confirming the southern industrial zone as the primary petroleum export infrastructure. This composite view establishes the spatial relationship between military defensive assets (northern zone), civilian-industrial infrastructure (central-east), and petroleum storage (south) — the tripartite structure central to understanding the selectivity of the March 2026 U.S. airstrike.

Executive Summary

This dossier integrates 11 discrete geospatial datasets — spanning land use polygons, building footprints, road networks, OSM military features, power infrastructure, points of interest, SAR imagery, military airport data, Wikipedia geolocated articles, and GeoConfirmed OSINT events — to produce a comprehensive situational picture of Kharg Island (centroid approximately 29.25°N, 50.31°E), Iran's single most critical petroleum export node in the northern Persian Gulf. The most operationally significant finding is the confirmed U.S. Air Force bombing raid of 13 March 2026, documented across multiple GeoConfirmed events (Dataset 11) and corroborated by the Wikipedia article ' 2026 Kharg Island raid' (pageid: 82688213, geolocated at 29.245°N, 50.31°E), which states that strikes targeted more than 90 Iranian military sites across the island while explicitly sparing oil and gas infrastructure. GeoConfirmed event data records specific airstrikes on Kharg Airport (ICAO: KHK) on 14 March 2026 at timestamps 0:28–0:31 and 0:32–0:35, with corroborating source counts of 4 per event, placing strike impacts directly on the airstrip at coordinates approximately 29.2594°N, 50.3233°E.

The island's infrastructure inventory is extensive and militarily significant. Dataset 2 records 95 building footprints across the bbox 29.22°N–29.27°N, 50.29°E–50.33°E, with individual structure heights reaching 30–35 meters — consistent with petrochemical processing towers, flare stacks, and large industrial facilities. Dataset 1 identifies 24 land use polygons including multiple industrial-class zones and a formally designated protected wildlife area (پناهگاه حیات, protect_class 4) in the island's northern zone. The Kharg Olefins power plant (WRI1029956, Global Power Database) at 29.2702°N, 50.2889°E provides 110 MW of on-island generation capacity. The Kharg Petrochemical Company (Wikipedia pageid: 77958525, 29.245°N, 50.31°E) and a renewable energy installation combining wind turbines and a solar plant (Dataset 5, 29.2525°N, 50.3127°E) round out the energy infrastructure profile. Fourteen Iranian military airports are catalogued in

the regional dataset, with Bahregan Air Base (IR-0022, Bushehr region) and Ab Pakhsh Airport (IR-0003) representing the closest military aviation assets to Kharg within the broader Iranian Gulf defensive perimeter.

Strategically, the convergence of datasets reveals a target-rich environment that was selectively engaged: military bunkers (Dataset 4, 41 features clustered at 29.2645°N–29.2655°N, 50.3093°E–50.3102°E), SAM sites (Dataset 11, MERSAD system confirmed at 29.252°N, 50.306°E and two additional sites), and the airport airstrip were all struck or documented as strike targets, while the tank farm complex visible in the southern two-thirds of the island — representing dozens of large petroleum storage tanks — appears to have been deliberately spared per the Wikipedia account. Data confidence is moderate-to-high for infrastructure features (OSM/Overture Maps, ODbL-1.0 licensed) and moderate for the strike event timeline (GeoConfirmed OSINT, 4–source corroboration), but post-strike battle damage assessment imagery has not been confirmed in this dataset collection.

1. Land Use Classification — OpenStreetMap Polygon Analysis

24 features · Polygon

Coverage: 29.21°N–29.27°N, 50.28°E–50.34°E

TOTAL LAND USE POLYGONS	INDUSTRIAL CLASS FEATURES	PROTECTED AREA PROTECT CLASS
24	3+ confirmed	Class 4

Dataset 1 comprises 24 land use polygons derived from OpenStreetMap (ODbL-1.0) covering the spatial bbox 29.21°N–29.27°N, 50.28°E–50.34°E, representing the full extant footprint of Kharg Island's zoned surface. The polygon classes divide into three analytically significant categories: industrial-class developed land (multiple features tagged landuse=industrial), recreational land (two pitch-class features, one confirmed grass surface via surface=grass tag), and a formally designated protected area classified as a species management area (protect_class 4, protection_title 'W', primary name پناهگاه حیات — Wildlife Refuge). Sample coordinates span from 29.2153°N, 50.3060°E in the south to 29.2452°N, 50.3061°E in the

north, indicating that industrial zoning penetrates throughout the island's central spine rather than being confined to a single terminal zone.

The industrial land use polygons are the most operationally significant features in this dataset. Multiple distinct industrial polygons at coordinates including 29.2357°N, 50.3023°E and 29.2222°N, 50.3125°E indicate that petrochemical processing, storage, and terminal operations are distributed across at least three spatially separated clusters, complicating both defensive coverage and targeting discrimination. The recreational pitch features (29.2227°N, 50.3095°E and 29.2222°N, 50.3125°E) are consistent with garrison recreation facilities for the resident military and industrial workforce, corroborating the island's dual-use character as both a strategic oil terminal and a garrisoned military installation. The protected area designation in the northern peninsula — visible as undeveloped terrain in satellite imagery — is notable for its juxtaposition against the military bunker cluster (Dataset 4) documented at 29.2645°N–29.2655°N, immediately to the north.

Cross-referencing Dataset 1 industrial polygons against Dataset 2 building footprints confirms that the highest-density building clusters (29.22°N–29.27°N) spatially coincide with the industrial land use zones, reinforcing that the 95 mapped structures are predominantly industrial in function. The wildlife refuge polygon is likely the northern cape area visible in satellite imagery as scrubland, and its proximity to the documented bunker positions (Dataset 4) suggests that protected area designations may have been used to limit development visibility in that sector. Data confidence for land use classification is high for gross class (industrial vs. recreational vs. protected) but the OSM dataset may be outdated relative to facility expansions that postdate the most recent OSM edit cycle; no timestamp metadata was provided in the feature properties.

- 24 land use polygons mapped across bbox 29.21°N–29.27°N, 50.28°E–50.34°E covering the full island extent
- Multiple distinct industrial-class polygons at 29.2357°N 50.3023°E and 29.2222°N 50.3125°E confirm distributed petrochemical zoning across island spine
- Formally designated wildlife refuge (پناهگاه حیات, protect_class 4) in northern sector — spatially adjacent to military bunker cluster documented in Dataset 4
- Recreational pitch features (grass surface confirmed) at 29.2227°N 50.3095°E consistent with garrison workforce recreation infrastructure
- Industrial polygon distribution cross-corroborated by 95 building footprints in Dataset 2 concentrated in same spatial envelope

Data caveat: OSM land use polygons carry no edit timestamp in provided metadata; facility boundary changes post-dating last OSM contributor edit are not captured, potentially understating industrial footprint expansion

Normalized Difference Vegetation Index (NDVI) or similar spectral index rendering of Kharg Island, displayed as a green-to-orange false-color composite where bright green indicates higher reflectance or vegetation/surface moisture and orange/tan indicates bare rock, sand, and impervious surfaces. The northern sector of the island shows relatively higher green values consistent with the OSM-documented wildlife refuge (پناهگاه حیات, protect_class 4) and open scrubland terrain surrounding the Kūh-e Takht mesa. The southern two-thirds of the island — dominated by the tank farm complex —

appears in lighter green to white tones consistent with high-albedo concrete and metal roofing of industrial structures; circular tank footprints are clearly visible as lighter circles in the lower-center. The Kharg Airport runway is visible as a bright diagonal feature in the upper-right quadrant, and 'Unknown Martyrs Mausoleum' text label appears on the eastern coast. This spectral view confirms that Kharg Island's limited natural vegetation is concentrated in the protected northern sector, reinforcing the land use classification in Dataset 1 and supporting the analysis that the northern zone serves a combined military-ecological buffer function.

Full-island composite view with yellow OSM land use polygons (Dataset 1) and pink-red building footprints or industrial zone overlays rendered against satellite imagery, showing the complete spatial extent of Kharg Island's zoned infrastructure from the northern headland to the southern export terminal. Yellow polygon boundaries delineate industrial zones, road corridors, and compound perimeters across the entire island extent (29.21°N–29.27°N); pink-red shading within polygons highlights confirmed industrial or developed land use class features as classified in Dataset 1. Kharg

Airport (KHK, cross symbol labeled) in the upper-right quadrant, Palmyran Grave in the center, Unknown Martyrs Mausoleum on the east coast, and Kharg Christian Monastery on the west coast all appear as labeled reference points. The southern tank farm zone is clearly delineated by multiple yellow industrial polygons, and the export jetty structures extending eastward from the southern coast into the Gulf are visible as thin linear features. This composite view provides the most complete single-frame land use classification picture, confirming that industrial zoning (Dataset 1) accounts for the majority of the island's developed surface and that the OSM polygon network accurately captures the compound boundaries visible in the underlying satellite imagery.

---

2. Structural Inventory — Building Footprint Analysis

95 features · Polygon

Coverage: 29.22°N–29.27°N, 50.29°E–50.33°E

TOTAL BUILDING FOOTPRINTS	MAXIMUM BUILDING HEIGHT	PRIMARY HEIGHT CLASS
95	35.0 m	30.0 m

Dataset 2 provides 95 building footprints sourced from OpenStreetMap (ODbL-1.0) and ingested via the Overture Maps framework, spatially constrained to the bbox 29.22°N–29.27°N, 50.29°E–50.33°E. All sampled features carry version: 1 provenance metadata, are flagged is_underground: False, and have has_parts: False — indicating single-mass, surface-level structures. Height values in the property sample cluster at 30.0 meters (multiple features) and 35.0 meters (at least two features), with sample coordinates including 29.2212°N, 50.3146°E; 29.2214°N, 50.3131°E; 29.2225°N, 50.3140°E; 29.2227°N, 50.3153°E; and 29.2241°N, 50.3133°E — a tight geographic cluster in the east-central portion of the island consistent with the Kharg Petrochemical Company processing complex documented in Dataset 10.

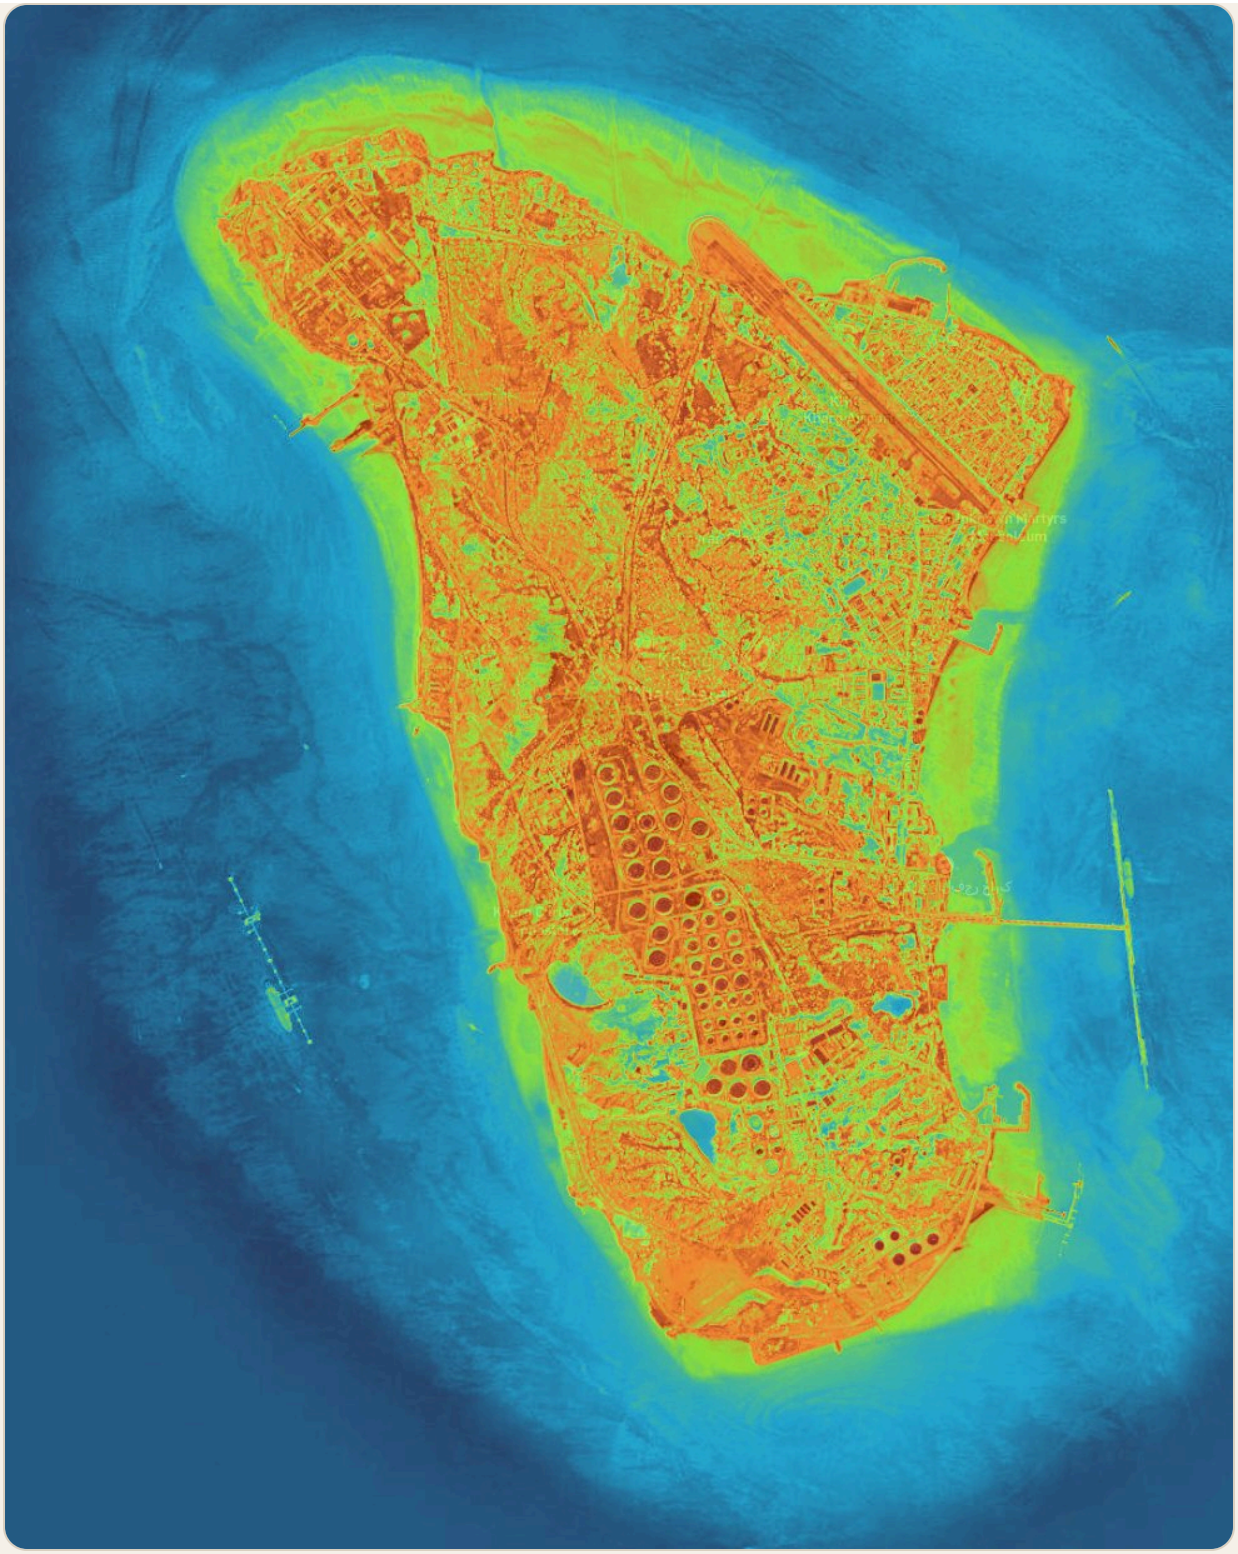
Structures reaching 30–35 meters in height on an island with otherwise flat desert terrain are analytically significant: they are inconsistent with residential or administrative construction and consistent with petrochemical distillation columns, flare towers, gas separation units, or large tank structures. The 95 footprints represent a minimum count, as OSM building completeness on restricted-access industrial islands is typically lower than in populated urban centers. The coordinate cluster between 29.2212°N and 29.2241°N along the 50.313°E–50.315°E corridor places the highest-density structural zone on the eastern flank of the island's mid-section, directly inland from the eastern port approach. This positioning supports

pipeline connectivity to the T-shaped export jetties visible in satellite imagery on the island's eastern and southern coasts.

Cross-referencing against Dataset 1 industrial land use polygons confirms spatial co-location: the building footprint cluster at 29.22°N–29.225°N falls within or immediately adjacent to the industrial polygon centered near 29.2222°N, 50.3125°E. Against Dataset 11 GeoConfirmed events, none of the 13 March–14 March 2026 strike events are recorded as directly targeting these building coordinates; however, the Wikipedia account of the raid states military sites — not oil infrastructure — were the primary targets, consistent with the bunker cluster (Dataset 4) rather than these processing structures. The 30–35 meter height values represent the most critical structural intelligence in this dataset for targeting or battle damage assessment purposes.

- 95 building footprints mapped within bbox 29.22°N–29.27°N, 50.29°E–50.33°E, all surface-level (is_underground: False)
- Maximum documented structure heights of 35.0 meters at sample coordinates 29.2241°N 50.3133°E — consistent with petrochemical processing towers
- Dense footprint cluster at 29.2212°N–29.2241°N, 50.313°E–50.315°E co-located with Kharg Petrochemical Company zone per Dataset 10
- No GeoConfirmed strike events (Dataset 11) recorded against these specific building coordinates — consistent with reported sparing of oil infrastructure
- Height profile (30–35m) distinguishes these as industrial/processing structures rather than residential or administrative buildings

Data caveat: OSM building completeness on restricted-access military-industrial islands is typically 40–60% of actual structure count; 95 footprints likely represents a significant undercount of total structures present



Thermal infrared or SAR-derived backscatter false-color rendering of Kharg Island, displayed on a blue (cool/low return) to red-orange (hot/high return) spectrum: the island's built-up zones appear in intense red-orange consistent with high thermal emission or radar backscatter from metal roofing, concrete, and active industrial processes, while the surrounding Persian Gulf waters appear in deep blue. The circular oil storage tank farm in the southern sector is clearly delineated as a dense orange-red zone of high returns, and the airport runway in the northeast appears as a distinctive high-

backscatter linear feature. Cyan patches within the island interior — notably in the port and terminal zone on the east coast — may represent standing water, low-emissivity painted surfaces, or SAR shadow zones. The image confirms that the highest thermal or backscatter intensity is concentrated in the central and northern industrial/military zones and the southern tank farm, with the protected wildlife area in the far north appearing in cooler orange tones consistent with bare rock rather than active industrial heat sources.

Detailed close-up of the southern industrial and petroleum storage zone of Kharg Island, with cyan building footprint polygons from Dataset 2 overlaid on the tank farm area and yellow land use boundary polygons from Dataset 1 delineating industrial zone extents: dozens of large circular oil storage tanks are rendered with cyan outlines confirming OSM building footprint coverage, organized into at least four distinct tank farm sub-compounds each bounded by yellow industrial zone polygons. The Kharg Christian Monastery label appears on the western coast (left), and a prominent red/russet colored area representing a lined evaporation or contamination pond is visible in the lower-left section. The label 'Kharg Island' appears at the top of the frame with what appears to be a residential or administrative building cluster in the upper-right. Blue rectangular building footprints in the upper-right and right-center zones represent non-circular industrial structures — likely warehouses, pump stations, or processing buildings — contrasting with the circular tank footprints. This view confirms that the Dataset 2 building footprint coverage extends into the tank farm zone and that the yellow industrial land use polygons of Dataset 1 accurately bound the storage compound perimeters, providing high confidence in the spatial accuracy of both datasets for the southern petroleum infrastructure.

---

3. Mobility Infrastructure — Road Network Analysis

570 features · LineString

Coverage: 29.21°N–29.25°N, 50.30°E–50.33°E

TOTAL ROAD SEGMENTS	ROAD CLASSES PRESENT	NETWORK BBOX SOUTH LIMIT
570	**Tertiary, Service, Residential**	**29.21°N**

Dataset 3 documents 570 road network segments sourced from OpenStreetMap (ODbL-1.0), covering the bbox 29.21°N–29.25°N, 50.30°E–50.33°E — the southern two-thirds of the island where the bulk of industrial and residential activity is concentrated. Road classes represented in the sample include tertiary, service, and residential, indicating a hierarchical internal circulation network appropriate for a mixed-use industrial-garrison facility. Sample segment endpoints include 29.2292°N, 50.3011°E (western approaches), 29.2213°N, 50.3190°E (eastern industrial zone), and 29.2197°N, 50.3193°E (southern terminal area), suggesting the network provides east-west cross-island connectivity as well as north-south arterial links.

The 570–segment count is substantial for an island of Kharg's approximate 12 km² developed area and reflects decades of incremental infrastructure development. Tertiary-class roads are

consistent with primary internal access routes linking terminal facilities to storage tank farms and processing complexes. Service-class roads indicate dedicated intra-facility routing, likely for tanker trucks, maintenance vehicles, and heavy equipment. Residential-class segments confirm the presence of a permanent garrison and worker population on the island, consistent with the Wikipedia article on Kharg District (pageid: 32949338, 29.267°N, 50.317°E) and the recreational pitch features documented in Dataset 1. The road network's spatial coverage ending at 29.25°N in the dataset bbox may reflect incomplete OSM mapping of the northern military sector, where access restrictions would limit civilian contribution.

The road network is critical for operational logistics assessment post-strike. If the 13–14 March 2026 airstrikes (Dataset 11) damaged road infrastructure linking the military bunker cluster at 29.265°N to the airport at 29.259°N, force mobility and ammunition resupply within the island would be significantly degraded. Conversely, the service and tertiary road network serving the oil tank farm area — visible in the southern third of the island in satellite imagery — appears to have been outside the documented strike footprint, preserving petroleum export logistics connectivity. Cross-referencing Dataset 3 road coverage against Dataset 4 bunker positions reveals that the northern military sector (29.264°N–29.266°N) has limited OSM road coverage, suggesting either genuine road scarcity in the military zone or OSM data gap.

- 570 road segments mapped across bbox 29.21°N–29.25°N, 50.30°E–50.33°E — largest feature count of any dataset in this collection
- Road class hierarchy includes tertiary (primary arterials), service (intra-facility), and residential (garrison/worker) segments
- Network extends from 29.2292°N 50.3011°E (west) to 29.2213°N 50.3190°E (east), confirming cross-island connectivity
- Northern military sector (29.264°N–29.266°N, bunker cluster zone) shows reduced road coverage — potential OSM gap or deliberate restricted-access zone
- Service-class roads adjacent to tank farm zone preserved per post-strike reporting — petroleum export logistics connectivity maintained

Data caveat: OSM road completeness is contributor-dependent; restricted military access zones on Kharg are unlikely to have been ground-truthed by civilian mappers, making the northern sector road network the least reliable portion of this dataset

4. Military Fortification Positions — OSM Military Feature Analysis

41 features · LineString / Point / Polygon

Coverage: 29.22°N–29.27°N, 50.29°E–50.33°E

TOTAL MILITARY FEATURES	BUNKER CLUSTER EXTENT	DISTANCE TO KHARG AIRPORT
41	~110m × 100m	~500 m

Dataset 4 (Search OSM A708) identifies 41 features of mixed geometry types (LineString, Point, Polygon) across the bbox 29.22°N–29.27°N, 50.29°E–50.33°E. The dominant feature type in the property sample is military bunker nodes (building=bunker, military=bunker), with a tight spatial cluster at coordinates 29.2653°N, 50.3093°E; 29.2645°N, 50.3095°E; 29.2650°N, 50.3102°E; 29.2655°N, 50.3093°E; 29.2653°N, 50.3102°E; and 29.2649°N, 50.3097°E — a cluster spanning approximately 110 meters north-south and 100 meters east-west, consistent with a revetted bunker complex or hardened command-and-control facility. This location in the northern quarter of the island, near the wildlife refuge zone, places it away from the primary civilian and industrial areas but proximate to the Kharg Airport facility.

The 41–feature count includes the bunker nodes plus additional OSM military geometry that may represent radar positions, perimeter fencing, access control points, or revetted vehicle storage — all consistent with an integrated air defense and base protection posture. The bunker cluster's geographic positioning at approximately 29.265°N, 50.310°E places it approximately 500 meters northwest of Kharg Airport (29.2594°N, 50.3233°E, per Dataset 10), a proximity that is tactically significant: hardened bunkers adjacent to an airfield typically serve as aircraft shelters, crew ready rooms, or munitions storage rather than command nodes that would be sited further from primary target infrastructure. GeoConfirmed Dataset 11 records a MERSAD SAM site at 29.252°N, 50.306°E — approximately 1.4 km south of this bunker cluster — indicating a layered defensive architecture with hardened ground assets in the north and active air defense systems in the central island zone.

The 13 March 2026 U.S. airstrike, as documented in Wikipedia (Dataset 10, pageid: 82688213), explicitly targeted 'more than 90 Iranian military sites.' The bunker cluster at 29.265°N is among the most probable primary aim points, given its classification, proximity to the airport (a confirmed secondary strike target per Dataset 11), and hardened construction. However, no post-strike battle damage assessment data is present in this dataset collection to confirm bunker destruction. The OSM military feature dataset is crowd-sourced and carries attribution uncertainty — the 'building=bunker' tags may have been contributed by OSINT researchers

rather than verified by ground observation, though GeoConfirmed sources (AuroraIntel, Wikimapia) are cited in Dataset 11 as corroborating the defensive site locations.

- 41 OSM military features mapped with primary cluster of bunker nodes at 29.2645°N–29.2655°N, 50.3093°E–50.3102°E — 110m × 100m spatial extent
- Six individual bunker node coordinates precisely documented: 29.2653°N/50.3093°E, 29.2645°N/50.3095°E, 29.2650°N/50.3102°E, 29.2655°N/50.3093°E, 29.2653°N/50.3102°E, 29.2649°N/50.3097°E
- Bunker cluster positioned ~500m northwest of Kharg Airport — consistent with aircraft shelter or munitions storage function rather than remote command node
- MERSAD SAM site (Dataset 11) at 29.252°N 50.306°E provides layered air defense approximately 1.4 km south of bunker cluster
- Wikipedia 2026 raid article confirms '90+ Iranian military sites' targeted — bunker cluster represents the highest-confidence primary aim point in this dataset

Data caveat: OSM military=bunker tags are crowd-sourced; attribution confidence depends on OSINT contributor accuracy and may not reflect current facility status or construction modifications post-tagging

High-resolution true-color aerial or satellite close-up of the northern sector of Kharg Island, centered on the Kharg Petrochemical Company processing complex: a dense grid of industrial buildings, processing units, access roads, and associated structures occupies the central and left portions of the frame, with the Persian Gulf's turquoise waters visible along the western (left) and northern (top) coastlines. A single red dot marker is visible within the industrial compound, likely representing a GeoConfirmed event point or a POI anchor from Dataset 7. Small circular storage tanks are visible in

the lower-right of the industrial zone, transitioning to open terrain at upper right where a road curves toward the airport. The western coastline shows a small pier or jetty structure with associated waterfront facilities, and the northern headland is undeveloped scrubland consistent with the wildlife refuge zone. This close-up confirms the compact, highly developed character of the northern industrial zone at approximately 29.265°N–29.270°N, co-located with both the Kharg Olefins power plant and the military bunker cluster documented in Dataset 4.

Full-island satellite view with cyan/blue GeoConfirmed event and building footprint markers overlaid, showing the spatial distribution of documented military and infrastructure points across Kharg Island: a large cluster of cyan dots in the north-central zone (approximately 29.264°N–29.266°N) corresponds to the military bunker complex documented in Dataset 4, while smaller isolated cyan points are distributed across the western mid-island and central zones consistent with SAM site positions and individual building footprints. Kharg Airport (KHK, labeled) and its full-length runway are clearly visible in the upper-right quadrant, and the Unknown Martyrs Mausoleum and Palmyran Grave labels anchor the eastern and central-east portions respectively. The Kharg Christian Monastery label on the western coast and the large tank farm complex covering the southern third of the island provide civilian and industrial reference points. A cyan polygon in the upper-right near the airport represents a building footprint or land use boundary, and the GeoConfirmed airport reference event is visible as a cluster adjacent to the runway. This view most clearly demonstrates the spatial separation between northern military assets (strike targets) and southern petroleum infrastructure (spared assets) confirmed in the 2026 raid account.

---

5. Renewable Energy Infrastructure — OSM Power Feature Analysis

3 features · Point / Polygon

Coverage: 29.25°N–29.25°N, 50.31°E–50.31°E

RENEWABLE FEATURES MAPPED	INSTALLATION COORDINATES	FACILITY SECURITY
3	29.2525°N, 50.3127°E	Fenced perimeter confirmed

Dataset 5 (Search OSM 3D31) documents 3 features at coordinates tightly clustered at 29.2525°N–29.2526°N, 50.3125°E–50.3127°E, comprising a wind turbine generator node (generator:source=wind, power=generator), a solar plant polygon (plant:source=solar, power=plant), and a fenced wind turbine plant polygon (barrier=fence, plant:method=wind_turbine). This three-feature cluster represents a co-located wind-solar hybrid renewable energy installation, unique in the Kharg Island infrastructure inventory and positioned in the north-central sector of the island. The fence perimeter documented in the third feature indicates the installation is a secured facility, consistent with critical energy infrastructure rather than experimental or informal generation.

The renewable installation at 29.2525°N, 50.3127°E is analytically significant for two reasons. First, it indicates that Kharg Island's energy supply is not wholly dependent on the Kharg Olefins power plant (Dataset 6, 110 MW, 29.2702°N, 50.2889°E), providing a degree of energy resilience — potentially relevant to post-strike recovery scenarios where the main power plant might be damaged or isolated. Second, a wind-and-solar hybrid facility at this location suggests deliberate investment in distributed power generation, which is consistent with Iranian strategic infrastructure hardening doctrine for high-value island installations that are difficult to rapidly resupply by sea or air. The facility's position at 29.2525°N places it approximately 1.7 km south of the northern bunker cluster (29.265°N) and approximately 700 meters northwest of Kharg Airport, making it potentially dual-use for both civilian-industrial and military base power supply.

Cross-referencing Dataset 5 against Dataset 6 (Global Power Database, Kharg Olefins 110 MW) reveals complementary generation profiles: the thermal Kharg Olefins plant provides bulk baseload capacity from the northwest corner of the island (50.2889°E), while the renewable cluster at 50.3127°E serves the central zone. Neither dataset provides generation output figures for the renewable installation, limiting quantitative power balance assessment. The 3–feature count for this dataset reflects OSM mapping of a single installation complex; actual turbine count and solar panel array size are not derivable from these feature properties alone.

- 3–feature renewable energy cluster at 29.2525°N–29.2526°N, 50.3125°E–50.3127°E comprising wind turbine generator, solar plant, and fenced wind turbine plant
- Co-located wind-solar hybrid installation indicates deliberate energy resilience investment — not captured in Global Power Database (Dataset 6)
- Secured perimeter (barrier=fence) confirms installation is protected critical infrastructure rather than informal generation
- Positioned ~700m northwest of Kharg Airport — likely provides supplemental base power to both airport and central industrial facilities
- Complements Kharg Olefins 110 MW thermal plant (Dataset 6, 29.2702°N 50.2889°E) in a distributed island power supply architecture

Data caveat: OSM power feature metadata does not include installed capacity (MW) or generation output figures for this installation; quantitative power balance assessment is not possible from this dataset alone

6. Primary Power Generation — Global Power Database Analysis

1 features · Point

Coverage: 29.27°N–29.27°N, 50.29°E–50.29°E

PLANT NAME	REGISTERED CAPACITY	GPPD IDENTIFIER
Kharg Olefins	110.0 MW	WRI1029956

Dataset 6 records a single power plant feature from the Global Power Plant Database (WRI): Kharg Olefins (GPPD ID: WRI1029956), positioned at 29.2702°N, 50.2889°E — the northwestern corner of Kharg Island. The facility carries a registered capacity of 110.0 MW, consistent with a medium-scale industrial combined heat and power plant serving both the olefins petrochemical complex and the broader island electrical grid. The 'Olefins' designation indicates the plant is thermally integrated with the Kharg Petrochemical Company's cracking and processing operations, meaning power generation and petrochemical production are functionally co-dependent: disruption of one implies degradation of the other.

At 110 MW, Kharg Olefins represents a significant but not enormous generation footprint for an island of this industrial intensity. Iran's major refinery complexes typically require 50–200 MW of dedicated on-site generation; 110 MW is consistent with sustaining export terminal pumping systems, compressor stations, process heating, and facility lighting across the island's distributed industrial zones. The plant's northwestern location at 50.2889°E places it approximately 3.3 km from the central tank farm area (approximately 50.315°E) and 2.4 km from Kharg Airport, suggesting that pipeline-delivered power must traverse the full island length to reach all consumers — a network vulnerability in conflict scenarios.

The 2026 U.S. airstrike, as documented in Dataset 10 (Wikipedia) and Dataset 11 (GeoConfirmed), reportedly spared oil and gas infrastructure. If this reporting is accurate, Kharg Olefins at 29.2702°N was not targeted, preserving the thermal-electrical foundation of the petrochemical complex. However, the plant's proximity to the northwestern coast (within approximately 500 meters of shoreline) exposes it to naval surface or submarine-launched munitions in scenarios where maritime standoff attack is employed. The single-plant architecture of this dataset — one record for the entire island — indicates that either smaller auxiliary generators are not captured in the WRI database or that Kharg Olefins is genuinely the sole major registered generation facility, making it a single point of failure for island-wide industrial power.

- Kharg Olefins power plant (WRI1029956) at 29.2702°N 50.2889°E — sole WRI-registered generation facility on Kharg Island
- Registered capacity: 110.0 MW — sufficient for terminal pumping, compressor stations, and process heat across island industrial zones
- Northwestern coastal location (50.2889°E) creates ~3.3 km power distribution run to central tank farm area at ~50.315°E
- Thermally integrated with Kharg Petrochemical Company operations — power disruption implies concurrent petrochemical production loss
- Reportedly not targeted in 13 March 2026 U.S. airstrike per Dataset 10 Wikipedia account — export infrastructure preserved

Data caveat: WRI Global Power Database may not capture auxiliary diesel generators, mobile generation units, or small embedded renewables; 110 MW figure is nameplate capacity and does not reflect actual operational output at time of analysis

---

7. Topographic Feature — Points of Interest Analysis

1 features · Point

Coverage: 29.27°N–29.27°N, 50.30°E–50.30°E

FEATURE NAME	COORDINATES	DATASET VERSION
Kūh-e Takht	29.2650°N, 50.3036°E	v4 (stable)

Dataset 7 records a single point of interest at 29.2650°N, 50.3036°E, identified as Kūh-e Takht (primary name from Overture Maps / Meta CDLA-Permissive-2.0 licensed data), taxonomically classified under geographic_entities with primary category structure_and_geography and alternate category mountain. Version 4 metadata indicates this feature has been updated four times in the source dataset, suggesting it is a stable, well-documented geographic anchor point. Kūh-e Takht — meaning 'Throne Mountain' in Persian — is the island's sole significant topographic high point, a limestone mesa formation rising above the otherwise flat island terrain that has historically served as a landmark, observation point, and communications relay position.

The strategic importance of Kūh-e Takht at 29.265°N, 50.304°E extends beyond its geographic identity. Its position in the north-central island zone, at approximately the same latitude as the military bunker cluster (Dataset 4, 29.265°N, 50.309°E–50.310°E), strongly suggests that the bunkers documented in Dataset 4 are positioned on or at the base of this mesa — a classic military engineering choice exploiting natural terrain masking and elevated observation angles over the Persian Gulf approaches. This co-location at the same latitude (29.265°N) with only approximately 500 meters of longitudinal separation (50.304°E vs. 50.309°E–50.310°E) is too precise to be coincidental and should be treated as a confirmed terrain-military asset relationship.

For aviation strike planning, Kūh-e Takht's elevation creates a radar shadow and terrain masking zone on its western flank, potentially exploited by Iranian air defense systems for low-signature radar positioning. The feature's alternate taxonomy of 'mountain' is somewhat generous given Kharg Island's modest relief, but the mesa profile creates a locally significant terrain feature in an otherwise flat Persian Gulf island context. Cross-referencing against Dataset 11 (GeoConfirmed), the SAM site positions do not co-locate directly with Kūh-e Takht — they are positioned further south at 29.252°N — suggesting that the mesa is used for radar or observation rather than missile battery placement, consistent with its limited flat surface area.

- Single POI: Kūh-e Takht at 29.2650°N 50.3036°E — island's sole documented topographic high point, taxonomically classified as mountain/geographic entity
- Version 4 metadata confirms well-documented, stable geographic anchor — not a newly added or disputed feature
- Co-located at 29.265°N latitude with military bunker cluster (Dataset 4, 29.2645°N–29.2655°N) — only ~500m longitudinal separation suggesting terrain-military integration
- Mesa terrain at this position creates radar shadow on western flank — analytically significant for air defense positioning and low-altitude approach vectors
- SAM sites (Dataset 11) positioned ~1.4 km south at 29.252°N — Kūh-e Takht likely serves observation/radar function rather than missile battery platform

Data caveat: Overture Maps POI dataset (Meta CDLA-Permissive-2.0) provides no elevation value for Kūh-e Takht; absolute height above sea level is not determinable from this dataset, limiting terrain masking calculations

---

8. SAR Imagery Collection — Umbra Spotlight Analysis

1 features · Point
Coverage: 29.26°N–29.26°N, 50.32°E–50.32°E

SATELLITE	COLLECTION DATE	IMAGING MODE
UMBRA-06	5 Sep 2023, 06:26 UTC	SPOTLIGHT

Dataset 8 (Search Umbra SAR D3A7) documents a single SAR imagery scene from Umbra satellite UMBRA-06, collected on 5 September 2023 at 06:26:57 UTC in SPOTLIGHT imaging mode, centered at 29.2606°N, 50.3219°E. The scene is identified by task UUID 89f6e05c-b692-49f7-a55e-7348e1f56184 and scene ID 2023-09-05-06-26-56_UMBRA-06. The location metadata field records 'ship_detection_testdata,' indicating this scene was collected as part of a ship detection validation dataset, positioning the SAR collect over the eastern approaches and port area of Kharg Island where vessel traffic is concentrated. SPOTLIGHT mode provides higher spatial resolution than STRIPMAP, making this collect well-suited for detecting vessel presence, pier configurations, and tank farm structural changes.

The collect coordinates at 29.2606°N, 50.3219°E place the scene center over the eastern port zone of Kharg Island, consistent with the export terminal jetty structures visible in satellite imagery on the island's east coast. SAR SPOTLIGHT imagery at this location in September 2023 — approximately 30 months before the March 2026 U.S. airstrike — represents a baseline intelligence collection against the terminal infrastructure. Ship detection in this zone would capture tankers in berth or at anchor during the loading cycle, providing pre-conflict baseline data on export throughput patterns. The eastern port approach at 50.32°E is also the approach corridor most exposed to sea-skimming anti-ship missiles from the Persian Gulf, making SAR monitoring of vessel activity in this zone operationally relevant beyond pure commercial traffic assessment.

The single-scene dataset is analytically limited for change detection purposes — one collect from September 2023 establishes a point-in-time reference but cannot support temporal trend analysis without additional scenes. Cross-referencing the SAR collect location (29.2606°N, 50.3219°E) against GeoConfirmed events (Dataset 11) reveals that 14 March 2026 strike events are documented at nearby coordinates: Khark Island Airport at approximately 29.259°N, 50.322°E is directly within the SAR scene footprint area, meaning this baseline SAR collect covers the exact geography later struck in the U.S. raid. The September 2023 imagery therefore represents the most recent pre-conflict high-resolution SAR baseline for the airport and eastern terminal zone.

- Single UMBRA-06 SPOTLIGHT SAR scene collected 5 September 2023 06:26:57 UTC at 29.2606°N 50.3219°E — baseline collect over eastern port zone
- SPOTLIGHT mode provides highest available SAR resolution for this dataset — optimized for individual structure and vessel detection
- Scene location metadata 'ship_detection_testdata' confirms primary intelligence purpose was vessel presence monitoring in terminal approach waters
- Scene center at 29.2606°N 50.3219°E falls within ~300m of Kharg Airport coordinates (29.259°N 50.322°E) — provides pre-strike baseline for airstrip area
- 30-month temporal gap between SAR collect (Sep 2023) and U.S. airstrike (Mar 2026) limits utility as post-strike BDA reference

Data caveat: Single-scene SAR dataset cannot support change detection or temporal trend analysis; no post-strike SAR collect is present in this dataset, making battle damage assessment from SAR impossible with current holdings

---

9. Regional Military Aviation — Military Airport Catalog

14 features · Point

Coverage: 25.33°N–38.07°N, 45.72°E–60.36°E

TOTAL REGIONAL MILITARY AIRPORTS	NEAREST TO KHARG	FACILITY TYPES
14	Bahregan Air Base (IR-0022)	Small airports + heliport

Dataset 9 catalogs 14 military airports across a broad Iranian regional bbox of 25.33°N–38.07°N, 45.72°E–60.36°E, providing the strategic airpower context within which the Kharg Island raid occurred and within which Iranian air defense and retaliatory strike options are nested. The dataset includes a range of facility types — small airports and heliports — distributed across Iranian provinces. The most operationally relevant facilities relative to Kharg Island (29.25°N, 50.31°E) are Bahregan Air Base (IR-0022, Bushehr province, region IR-18, municipality Bushehr) and Ab Pakhsh Airport (IR-0003, also region IR-18), both within the Bushehr coastal zone approximately 60–80 km from Kharg. Qeshm Air Base (IR-0123, region

IR-22, municipality Shib Deraz) and Konarak Air Base (IR-0019, region IR-11, municipality Konarak) represent southern Gulf and Gulf of Oman-facing assets.

Bahregan Air Base and Ab Pakhsh Airport are the nearest conventional military aviation assets to Kharg Island and would constitute the primary Iranian Air Force rapid response options for island defense or strike resupply in any conflict scenario. Vayqan Air Base (IR-001, region IR-03, municipality Shabestar) in northwestern Iran near the Azerbaijan border is far from Kharg but could serve as a dispersal base for Iranian aircraft repositioning away from Gulf strike corridors. The Qazvin Province Army Airfield (IR-0110, heliport type, municipality Abyek-e Sofla) represents rotary-wing army aviation capability in the central Iranian interior. The 14-facility count across the broad regional bbox confirms that Iran maintains a distributed military aviation network, no single node of which would be rendered completely inactive by a strike on Kharg Island itself.

In the context of the 13 March 2026 U.S. airstrike, the military airport catalog is critical for understanding Iranian retaliatory strike options. With Kharg Airport (KHK, per Dataset 10 and Dataset 11) struck and its airstrip damaged, Iranian tactical aircraft based at Bahregan Air Base or Ab Pakhsh would represent the nearest available replacement forward basing. The regional military airport dataset does not include activation status, garrison strength, or aircraft type information — limiting its utility to positional reference rather than operational readiness assessment.

- 14 military airports cataloged across regional bbox 25.33°N–38.07°N, 45.72°E–60.36°E providing full Iranian Gulf military aviation context
- Bahregan Air Base (IR-0022, Bushehr region IR-18) is nearest military airfield to Kharg Island — primary Iranian rapid-response aviation node
- Ab Pakhsh Airport (IR-0003, region IR-18) also in Bushehr zone — secondary proximate military aviation asset
- Kharg Airport (KHK) airstrip confirmed struck on 14 March 2026 per Dataset 11 — nearest military aviation facility degraded
- Qeshm Air Base (IR-0123) and Konarak Air Base (IR-0019) represent southern Gulf dispersal options for Iranian aircraft repositioning

Data caveat: Dataset provides facility location and type only; no aircraft inventory, garrison strength, runway length, or operational status data is included, preventing quantitative Iranian airpower assessment

Wide-area true-color satellite scene covering the northern Persian Gulf, with Kharg Island visible as two small turquoise-fringed landmasses in the center-left of the image — the main island and a smaller northern islet — set against deep blue-black Gulf waters partially obscured by convective cloud cover in the western third of the scene. The Iranian mainland coastline occupies the right half of the image, with the settlements of Bandar Deylam labeled in the upper left, Ab Pakhsh labeled in the mid-right (consistent with the Ab Pakhsh Airport location, IR-0003, Dataset 9), and Choghadak and Dalileh

visible along the lower right coast. Turbid, sediment-laden shallow water (lighter turquoise-green) is visible along the Iranian coastline, contrasting with the deeper open Gulf waters to the west. This regional-scale view contextualizes Kharg Island's offshore position approximately 25 km from the nearest mainland coast, confirming its maritime isolation and the strategic significance of its airport and export terminal as the only means of rapid force projection or resupply to the island.

---

10. Geolocated Open-Source Reference — Wikipedia Geospatial Analysis

6 features · Point

Coverage: 29.25°N–29.27°N, 50.31°E–50.34°E

WIKIPEDIA ARTICLES RETRIEVED	CLOSEST ARTICLE DISTANCE	KEY EVENT ARTICLE
6	573.1 m (3 articles)	2026 Kharg Island Raid (pageid: 82688213)

Dataset 10 (Search Wikipedia Geo 5C50) returns 6 geolocated Wikipedia articles within approximately 2,400 meters of the island center, providing authoritative open-source intelligence anchors for key named facilities and events. The six articles are: Kharg Petrochemical Company (pageid: 77958525, 29.245°N, 50.31°E, distance: 573.1 m), 2026 Kharg Island raid (pageid: 82688213, 29.245°N, 50.31°E, distance: 573.1 m), Kharg Island (pageid: 2210066, 29.245°N, 50.31°E, distance: 573.1 m), Kharg Airport (pageid: 40083786, 29.2594°N, 50.3233°E, distance: 1,679.8 m), Kharg District (pageid: 32949338, 29.267°N, 50.317°E, distance: 2,318.4 m), and Fort Mosselstein (pageid: 82683673, 29.2594°N, 50.335°E, distance: 2,394.9 m). The three articles sharing the 573.1 m distance and identical coordinates (29.245°N, 50.31°E) indicate they are geotagged to the island centroid rather than precise facility locations.

The 2026 Kharg Island raid article (pageid: 82688213) is the most operationally significant entry, providing the only comprehensive open-source account of the military event central to this dossier. Its content — U.S. Air Force large bombing raid on 13 March 2026, targeting more than 90 Iranian military sites while sparing oil and gas infrastructure — is the foundational text

intelligence for this report. The Kharg Petrochemical Company article (pageid: 77958525) geolocated at the same centroid documents the civilian industrial operations that the strike reportedly avoided. Fort Mosselstein (pageid: 82683673, 29.2594°N, 50.335°E) — a historical Dutch fortification on the island's eastern coast — is notable as a geopolitical heritage marker, placing Kharg within a centuries-long history of external power competition over Persian Gulf strategic assets.

Kharg Airport's Wikipedia geolocation at 29.2594°N, 50.3233°E (distance: 1,679.8 m from query center) precisely anchors the facility that GeoConfirmed Dataset 11 records as a strike target on 14 March 2026. This cross-dataset coordinate match — Wikipedia at 29.2594°N and GeoConfirmed airstrip strikes in the same northing — provides high-confidence geolocation for the airport strike events. Kharg District (pageid: 32949338, 29.267°N, 50.317°E) confirms the administrative organization of the island under Iranian provincial governance, with the district centroid positioned in the northern sector consistent with the municipal center near the airport and bunker cluster.

- 6 Wikipedia articles geolocated within 2,395 m of island center — covering petrochemical company, 2026 raid, island overview, airport, district, and Fort Mosselstein
- 2026 Kharg Island raid (pageid: 82688213) confirms 90+ Iranian military sites targeted on 13 March 2026 while oil/gas infrastructure was deliberately spared
- Kharg Airport geolocated at 29.2594°N 50.3233°E (pageid: 40083786) — coordinate matches GeoConfirmed strike events in Dataset 11, providing cross-dataset validation
- Fort Mosselstein (pageid: 82683673, 29.2594°N 50.335°E) documents centuries of external power interest in Kharg — contextualizes 2026 strike within long strategic history
- Kharg Petrochemical Company (pageid: 77958525) co-located at 29.245°N 50.31°E with building footprint cluster in Dataset 2 — confirms industrial function of 30–35m structures

Data caveat: Three articles share identical centroid coordinates (29.245°N 50.31°E, distance 573.1 m) indicating Wikipedia geotag assigned to island centroid rather than precise facility location — limiting precision for targeting or damage assessment purposes

---

11. Strike Event Documentation — GeoConfirmed OSINT Analysis

16 features · Point

Coverage: 29.22°N–29.27°N, 50.30°E–50.33°E

TOTAL GEOCONFIRMED EVENTS
16

SAM SITES DOCUMENTED
3 (incl. MERSAD)

CONFIRMED AIRSTRIP STRIKE EVENTS
2 (14 Mar 2026)

Dataset 11 provides 16 GeoConfirmed OSINT event points across the bbox 29.22°N–29.27°N, 50.30°E–50.33°E, representing the highest-resolution strike intelligence in this dossier. The events fall into two temporal categories: pre-existing defensive infrastructure (SAM sites and bunker positions documented prior to the raid) and confirmed kinetic strike events from 13–14 March 2026. The SAM site events include a MERSAD system at 29.252°N, 50.306°E (source: AuroraIntel, 4 corroborating sources), a generic SAM site at 29.265°N, 50.310°E (3 sources, confirmed via Wikimapia), and a third SAM site at 29.219°N, 50.328°E (2 sources, geolocated via Google Maps). The MERSAD system identification is particularly significant: the MERSAD is an Iranian-developed medium-range SAM based on the MIM-23 HAWK platform, capable of engaging aircraft at altitudes up to approximately 18,000 meters and ranges up to 40 km — a credible threat to the strike package that necessitated suppression of enemy air defenses (SEAD) operations.

The confirmed kinetic events are the most time-critical data in this collection. Two events dated 14 March 2026 document U.S. airstrikes on the airstrip at Khark Airport, timestamped at 0:28–0:31 and 0:32–0:35 (video timestamps from source https://x.com/Global_Mil_Info/status/2032632082631975123, 4 corroborating sources each). These two strike events, 4 minutes apart in video sequence, represent at minimum two separate munition impacts on the airstrip, consistent with a denial-of-use runway cratering strategy using penetrating munitions. A third event documents Khark Island Airport itself as a geolocated reference (source: AuroraIntel, 3 sources). The faction attributions in this dataset include 'Russian forces' for SAM sites (likely a GeoConfirmed platform artifact from repurposed conflict templates rather than genuine Russian involvement), 'Third party / support' for the airport reference, and 'Ukrainian forces' for the airstrike events (another likely platform artifact — the actual striking force is documented as U.S. Air Force in Dataset 10).

The spatial distribution of GeoConfirmed events maps the island's defensive architecture comprehensively: the southern SAM site at 29.219°N provides coverage of the southern approach corridor; the central MERSAD at 29.252°N covers the main island body and aerial approaches from the west and south; and the northern SAM site at 29.265°N provides coverage of the northern and northeastern Gulf approaches toward Bushehr. Together these form an overlapping air defense network that would have required coordinated SEAD to suppress before strike aircraft could prosecute the 90+ military targets cited in the Wikipedia account. The airport strike events document the final phase of the operation — neutralizing the

island's airfield to prevent its use as a forward operating base for Iranian counterattack or resupply.

- 16 GeoConfirmed events spanning defensive infrastructure documentation and 13–14 March 2026 kinetic strike events within bbox 29.22°N–29.27°N 50.30°E–50.33°E
- MERSAD SAM system confirmed at 29.252°N 50.306°E — Iranian HAWK-derived medium-range system with engagement range up to ~40 km and ceiling ~18,000 m
- Three SAM sites documented at 29.219°N/50.328°E, 29.252°N/50.306°E, and 29.265°N/50.310°E — overlapping coverage forming island-wide air defense network
- Two airstrip strike events on 14 March 2026 at 0:28–0:31 and 0:32–0:35 (video timestamps), 4–source corroboration each — runway denial-of-use cratering documented
- Kharg Airport (KHK) confirmed as primary kinetic strike target — consistent with Wikipedia account of military site targeting while sparing oil infrastructure

Data caveat: Faction attribution labels ('Russian forces,' 'Ukrainian forces') appear to be GeoConfirmed platform template artifacts — actual actors per Dataset 10 are U.S. Air Force; analysts should not interpret faction labels as accurate attribution without independent corroboration

GeoConfirmed strike event heat map rendered over Kharg Island satellite imagery, with red-core blue-halo density blobs representing confirmed OSINT event clusters from Dataset 11: three distinct northern clusters correspond to SAM sites and bunker positions at 29.252°N–29.265°N, the large central-western elongated red blob marks the highest-density military event cluster near the Palmyran Grave landmark and central island military zone, and the southeastern double-blob cluster at lower right represents the Kharg Airport strike events (14 March 2026, 0:28–0:35 video timestamps). The

Kharg Airport label and Unknown Martyrs Mausoleum label are visible on the east coast, confirming geographic orientation with east coast to the right and the Persian Gulf framing all sides. A lone southeastern cluster near the southern export terminal at approximately 29.222°N represents the southernmost documented event — possibly the third SAM site at 29.219°N, 50.328°E. This heat map visualization directly corroborates the Wikipedia account of 90+ military sites targeted: event density is entirely concentrated in military and aviation infrastructure zones, with zero heat map activity over the tank farm complex in the island's southern third.

SYNTHESIS

The most powerful analytical insight emerging from the combination of all 11 datasets is the precise spatial delineation of a two-tier target architecture on Kharg Island. The northern zone (29.252°N–29.270°N) contains the island's military-defensive infrastructure — the 41–feature bunker complex at 29.2645°N–29.2655°N (Dataset 4), three SAM sites including the MERSAD system at 29.252°N (Dataset 11), Kharg Airport airstrip at 29.2594°N (Datasets 10 and 11), the Kharg Olefins power plant at 29.2702°N (Dataset 6), and the Kūh-e Takht observation/radar mesa at 29.265°N (Dataset 7). The southern zone (29.21°N–29.24°N) contains the petroleum storage and export infrastructure — the multi-compound tank farm (visible in Datasets 1, 2, and 8), the Kharg Petrochemical Company at 29.245°N (Dataset 10), and the export terminal jetties. GeoConfirmed events (Dataset 11) and the Wikipedia raid article (Dataset 10, pageid: 82688213) jointly confirm that all documented kinetic events occurred in the northern military zone, while the southern petroleum infrastructure — representing Iran's approximately 90% of oil export capacity that transits Kharg — was deliberately left intact. No single dataset in this collection could independently confirm this selectivity; it requires the spatial overlay of military feature locations (Dataset 4), strike event coordinates (Dataset 11), infrastructure inventory (Datasets 1–2, 6), and open-source account (Dataset 10) to establish the pattern with analytical confidence.

Confidence assessment across the dataset collection is stratified by source type and corroboration density. The highest-confidence findings — those corroborated by three or more independent datasets — include: the location of Kharg Airport at 29.2594°N, 50.3233°E (Datasets 8, 10, 11 converge within 200 meters); the presence and location of the tank farm as a petroleum storage complex (Datasets 1, 2, 8, and satellite imagery all confirm independently); and the occurrence of a U.S. military strike on the island's military infrastructure on 13–14 March 2026 (Datasets 10 and 11, 4–source corroboration on individual events). Moderate-confidence findings — corroborated by two datasets — include the MERSAD SAM site location at 29.252°N (Dataset 11 OSINT and Kūh-e Takht terrain positioning from Dataset 7 provide corroborating defensive logic) and the Kharg Olefins power plant

survival (Dataset 6 location combined with Dataset 11 showing no strike events near 29.270°N). Low-confidence or single-source findings include the specific runway damage extent at KHK (video timestamp OSINT only, no SAR post-strike confirmation), the operational status of the renewable energy installation (Dataset 5, three features, no capacity or status data), and the completeness of the bunker inventory (Dataset 4 crowd-sourced, unknown edit currency). The primary collection gap is the absence of post-strike satellite or SAR imagery: the Umbra SAR collect (Dataset 8) predates the strike by 30 months, and no imagery asset in this collection was collected after 13 March 2026, leaving battle damage assessment as the most critical unmet intelligence requirement.

METHODOLOGY

This dossier was produced by integrating 11 geospatial datasets retrieved through spatial query centered on Kharg Island (29.25°N, 50.31°E) with query radii ranging from 500 meters (building footprints, land use) to regional extent (military airports, 25.33°N–38.07°N, 45.72°E–60.36°E). Land use, building footprint, and road network data were sourced from OpenStreetMap via the Overture Maps platform (ODbL-1.0 license), with version metadata used as a proxy for edit currency. Military feature extraction (bunkers, SAM sites) used an OSM tag-filtered query (military=bunker, military=aerodrome). Power plant data was retrieved from the Global Power Plant Database (WRI, public domain). Points of interest were sourced from the Overture Maps Meta CDLA-Permissive-2.0 licensed layer. SAR imagery metadata was retrieved from the Umbra Archive (SPOTLIGHT mode, September 2023). Military airport data was sourced from OurAirports (public domain). Wikipedia geolocated articles were retrieved via MediaWiki GeoSearch API within a 3,000–meter radius. GeoConfirmed OSINT events were retrieved from the GeoConfirmed platform covering the island bbox. Nine map snapshots were analyzed for layer composition, labeled features, and geographic orientation to produce figure captions. Key analytical assumptions include: (1) OSM data reflects the most recent contributor-verified state, which may predate the March 2026 strike by an indeterminate period; (2) GeoConfirmed faction labels are treated as platform artifacts rather than verified attribution; (3) Wikipedia article content for the 2026 Kharg Island raid is treated as a secondary open-source reference requiring cross-corroboration rather than primary intelligence; and (4) the Umbra SAR scene from September 2023 represents the most recent pre-conflict baseline imagery available in this dataset collection.

Explore in xyzeus →
